The FTO gene harbors variation with the strongest effect on adiposity and obesity risk. Previous data support a role for FTO variation in influencing food intake. We conducted a combined analysis of 16,094 boys and girls aged 1–18 years from 14 studies to examine the following: 1) the association between the FTO rs9939609 variant (or a proxy) and total energy and macronutrient intake; and 2) the interaction between the FTO variant and dietary intake, and the effect on BMI. We found that the BMI-increasing allele (minor allele) of the FTO variant was associated with increased total energy intake (effect per allele = 14.3 kcal/day [95% CI 5.9, 22.7 kcal/day], \( P = 6.5 \times 10^{-4} \)), but not with protein, carbohydrate, or fat intake. We also found that protein intake modified the association between the FTO variant and BMI (interactive effect per allele = 0.08 SD [0.03, 0.12 SD], \( P \) for interaction = 7.2 \( \times 10^{-4} \)): the association between FTO genotype and BMI was much stronger in individuals with high protein intake (effect per allele = 0.10 SD [0.07, 0.13 SD], \( P = 8.2 \times 10^{-10} \)) than in those with low intake (effect per allele = 0.04 SD [0.01, 0.07 SD], \( P = 0.02 \)). Our results suggest that the FTO variant that confers a predisposition to higher BMI is associated with higher total energy intake, and that lower dietary protein intake attenuates the association between FTO genotype and adiposity in children and adolescents.
fat mass and obesity (FTO) are the first adiposity/BMI-associated variants identified through genome-wide association studies (GWASs) (1–3), and to date this remains the locus with the largest influence on BMI in adults, as well as in children and adolescents (4). The mechanism by which FTO variants influence adiposity is unclear. Previous animal studies have suggested a role of Fto in regulating energy homeostasis, but it is unknown whether it influences energy intake (5,6) or energy expenditure (7,8). In addition, it is not clear which gene’s function is affected by the functional variants at this locus: FTO itself or another gene located downstream or upstream of FTO, such as IRX3 (9) and RPGRIP1L (10).

In many human studies (11–20), the BMI-increasing allele of FTO variants has been reported to be associated with increased food intake, total energy intake, fat or protein intake, suggesting that diet mediates the association with BMI. However, these associations have not been replicated in a number of other studies (21–35). In addition, there is an increasing interest in examining whether lifestyle factors influence the associations between FTO variants and adiposity. While there is evidence that physical activity reduces the effect of FTO on BMI, at least in adults (36), the few studies (12,20,26,32,34,35,37,38) that have investigated interaction with dietary factors in relation to BMI/obesity have generated conflicting results regarding potential interactions. Our recent large-scale meta-analysis (39) indicated that FTO variants were associated with protein intake in adults and that under-reporting of dietary intake in obese participants might be a major issue in the analysis. Studies in children are of particular interest in this regard, since this population is less biased by comorbidities, and their treatment and exposure to environmental contributors is shorter.

The relatively small sample size of individual studies, the modest genetic effect size, and the inevitable measurement errors might be major reasons for these inconsistent observations. Thus, studies with larger sample sizes are needed to clarify interrelations among FTO variants, dietary intake, and adiposity. Herein we report the results of a combined analysis of 16,094 children and adolescents from 14 studies to examine the following: 1) whether the FTO rs9939609 variant (or a proxy SNP) is associated with dietary intake of total energy and macronutrients (protein, carbohydrate, and fat); and 2) whether dietary intake influences the association between the FTO variant and BMI.

RESEARCH DESIGN AND METHODS

Study Participants

The current analysis included cross-sectional data on 16,094 children and adolescents (15,352 whites, 478 African Americans, and 267 Asians) aged 1–18 years from 14 studies (Supplementary Table 1). The study design, recruitment of participants, and data collection of individual studies have been described in detail previously (14,23,24,40–50). In each study, informed consent was obtained from subjects’ parents or guardians and subjects (if appropriate). Each study was reviewed and approved by the local institutional review board.

Study-specific characteristics for each study are shown in Supplementary Table 2. The ranges of mean values across studies were as follows: age 1.1–16.4 years; BMI 16.2–24.7 kg/m²; total energy intake 1,017–2,423 kcal/day; total protein intake 12.9–16.8% (percentage of total energy intake); total carbohydrate 43.4–59.0%; and total fat intake 28.1–40.0%.

Assessment of BMI and Dietary Intake

BMI was calculated as body weight (kg)/height (m²). Body weight and height were measured in all studies except for one study which used self-reported data in a subsample (Supplementary Table 3). For two studies (43,48) with children younger than 2 years of age, length (height) was measured to the nearest millimeter with children in a supine position. Dietary intake (total energy, protein,
carbohydrate, and fat) was assessed using validated food frequency questionnaires (four studies), multiple-day dietary/food records (three studies), multiple-day 24-h recalls (four studies), both dietary records and 24-h recalls (one study), diet history determined by consulting and information system (one study), or a brief-type self-administered diet history questionnaire (one study) (Supplementary Table 3). Macronutrient intake was expressed as the percentage of total energy intake.

**Genotyping**

FTO SNP rs9939609 or a proxy (linkage disequilibrium \( r^2 = 1 \) in the corresponding ethnic group) was genotyped using direct genotyping methods or Illumina genome-wide genotyping arrays, or imputed using MACH (http://csg.sph.umich.edu/abecasis/MACH/) with a high imputation quality (\( r^2 = 1 \)) (Supplementary Table 4). The studies provided summary statistics based on data that met their quality control criteria for genotyping call rate, concordance in duplicate samples, and Hardy-Weinberg equilibrium \( P \) value.

**Statistical Analysis**

A standardized analytical plan, which is described below, was sent to study analysts from the 14 studies, and analyses were performed locally. BMI was transformed to age-standardized \( z \) score by sex in each study before analysis. A linear regression model under additive allelic effects was applied to examine associations of FTO variant with BMI, total energy intake, and intake of fat, protein, and carbohydrate (expressed as the percentage of total energy), adjusted for pubertal status (if available), physical activity (if available), and eigenvectors (data from GWASs only). We additionally adjusted for BMI when evaluating the association between FTO variant and dietary intake. In addition, the difference in BMI between the low- and high–dietary intake groups (dichotomized at medians in each study) was also examined. Interactions between FTO genotype and dietary intake and their effect on BMI were tested by including the respective interaction terms in the models (e.g., interaction term = rs9939609 SNP \( \times \) total energy intake [dichotomized at the medians in each study]). We examined the association between FTO variant and BMI stratified by low– and high–dietary intake groups (dichotomized at medians in each study). All of the analyses were conducted in boys and girls separately, except for one study that combined the data from boys and girls, with sex as a covariate. Analyses were also conducted in each race, and in cases and controls separately if studies included multiple ancestries or had a case-control design.

Detailed summary statistics from each study were subsequently collected, and we pooled \( \beta \)-coefficients and SEs from individual studies using the Mantel-Haenszel fixed-effects method, as well as the DerSimonian and Laird random-effects method implemented in Stata, version 12 (StataCorp LP, College Station, TX). The significant \( P \) value was 0.005 after Bonferroni adjustment for 10 independent tests: FTO-BMI association (1 test); diet-BMI associations (3 tests; we considered total energy, protein, carbohydrate, and fat intake as 3 independent variables); FTO-diet associations (3 tests); and FTO-diet interactions (3 tests). Between-study heterogeneity was tested by the Cochran \( Q \) statistic and quantified by the values for the proportion of variance explained by interstudy differences (\( I^2 \)). Low heterogeneity was defined as an \( I^2 \) value of 0–25%, moderate heterogeneity as an \( I^2 \) of 25–75%, and high heterogeneity as an \( I^2 \) of 75–100%. The \( P \) value for heterogeneity was derived from a \( \chi^2 \) test. We also performed stratified meta-analyses in subgroups according to ethnicity (whites, African Americans, or Asians), sex, age group (mean age <10 vs. \( \geq 10 \) years), geographic region (North America, Europe, or Asia), study sample size (\( n < 500 \) vs. \( n \geq 500 \)), study design (population based vs. case-control), dietary intake assessment method (dietary records or 24-h recalls vs. food frequency questionnaire or others), and adjustment for physical activity (yes vs. no).

**RESULTS**

**FTO Variants and BMI**

We found a significant association between the minor allele (A-allele) of the FTO SNP rs9939609 (or its proxies) and a higher BMI in all participants combined (effect per allele =

Data are \( \beta \)-coefficients (95% CI) per minor allele of FTO rs9939609 or a proxy (\( r^2 = 1 \)) are given for each trait. Analyses from individual studies were conducted separately and then combined by meta-analysis of 16,097 children and adolescents (15,352 whites, 478 African Americans, and 267 Asians). \( I^2 \) values are also given. *Adjusted for age, pubertal status (if available), physical activity (if available), region (if available), and eigenvectors (GWAS data only). †Further adjusted for BMI based on model 1.
0.07 SD [95% CI 0.05, 0.09 SDs], \( P = 4.7 \times 10^{-10} \) (Table 1). The association was significant in 15,352 whites (effect per allele = 0.08 SD [0.05, 0.10 SDs], \( P = 2.9 \times 10^{-11} \)), but not in 478 African Americans (effect per allele = \(-0.12 \) SD [\(-0.26, 0.02 \) SDs], \( P = 0.08 \)) or 267 Asians (effect per allele = 0.11 SD [\(-0.12, 0.09 \) SDs], \( P = 0.87 \)), separately.

**FTO Variants and Dietary Intake**

The minor allele of the *FTO* variant was significantly associated with higher total energy intake in all participants combined (effect per allele = 14.6 kcal/day [6.3, 23.1 kcal/day], \( P = 0.65 \times 10^{-4} \)), with no heterogeneity among studies (\( I^2 = 0 \% \)) (Table 1). This association was unchanged after further adjustment for BMI (effect per allele = 14.7 kcal/day [6.3, 23.1 kcal/day], \( P = 0.65 \times 10^{-4} \)). The association between *FTO* variant and total energy intake was found in whites (\( P = 0.001 \)) and Asians (\( P = 0.01 \)), but not in African Americans (\( P = 0.80 \)), although directions of associations were consistent across ethnicities (\( P \) for heterogeneity = 0.07) (Fig. 1). In stratified meta-analyses according to sex, age group, geographic region, study design, dietary intake assessment...
method, and adjustment for physical activity (Supplementary Fig. 1), the directions of the associations between FTO variant and total energy intake were consistent across subgroups. Of note, the association was stronger in studies with a mean age for participants of ≥10 years than in studies with a mean age of <10 years (effect per allele = 25.3 vs. 4.2 kcal/day, $P$ for heterogeneity = 0.014). Since most studies had a mean age for participants of >7.5 years and three studies had a mean age between 1.0 and 3.5 years, we further examined the association between FTO variant and total energy intake across subgroups. Of note, the association was stronger in studies with a mean age for participants of ≥10 years old (effect per allele = 25.3 kcal/day).

We did not find evidence for associations between FTO variant and intake of protein ($P = 0.10$), carbohydrate ($P = 0.96$), or fat ($P = 0.40$), and there was a low or moderate heterogeneity among studies ($I^2 = 0\%$, 24\%, and 34\%, respectively) (Table 1 and Supplementary Figs. 2, 3, and 4). Further adjustment for BMI did not notably change the results.

We also performed meta-analyses for FTO variant and dietary intake using the random-effects method, resulting in similar findings (Supplementary Table 5).

### Dietary Intake and BMI

Higher total energy and protein intake were significantly associated with higher BMI (Supplementary Table 6). Difference in BMI between the high and low energy intake groups was 0.04 SD (95\% CI 0.01, 0.02 SDs, $P = 0.004$), and difference in BMI between the high-protein intake and low-protein intake groups was 0.09 SD (0.07, 0.12 SDs, $P = 5.0 \times 10^{-15}$). There was no significant difference in BMI between the high-carbohydrate intake and low-carbohydrate intake groups (difference in BMI = −0.02 SD [−0.05, 0.01 SDs], $P = 0.12$), and a nominally significant difference in BMI between the high-fat intake and low-fat intake groups (difference in BMI = −0.03 SD [−0.06, −0.001 SDs], $P = 0.04$).

#### Interaction Between FTO Variants and Dietary Intake on BMI

We observed a significant interaction between FTO variant and dietary protein intake on BMI in all participants combined (effect per allele for interaction = 0.08 SD [95\% CI 0.03, 0.12 SDs], $P$ for interaction = 7.2 × 10^{-4}), showing that lower protein intake attenuated the association between the FTO variant and BMI, with no heterogeneity among studies ($I^2 = 0\%$) (Table 2). In stratified analysis by low-protein intake and high-protein intake groups (dichotomized at medians of protein intake in each study: ranging from 12.9\% to 16.8\% across studies). The association between FTO variant and BMI among participants in the low-protein intake group (effect per allele = 0.04 SD [95\% CI 0.01, 0.07 SDs], $P = 0.02$) was significantly weaker than that in the high-protein intake group (effect per allele = 0.10 SD [0.07, 0.13 SDs], $P = 8.2 \times 10^{-10}$) (Table 2). Although the interaction was found in whites ($P$ for interaction = 0.001) but not in African Americans ($P = 0.84$) or Asians ($P = 0.11$) separately, there was no significant heterogeneity among these ethnic groups ($P$ for heterogeneity = 0.53) (Fig. 2). In stratified meta-analyses (Supplementary Fig. 5), we found similar interaction patterns between FTO variant and protein intake on BMI across subgroups divided by sex, age group, geographic

Data are $\beta$-coefficients (95\% CI) per minor allele of FTO rs9939609 or a proxy ($r^2 = 1$) for BMI ($z$ score), adjusted for age, pubertal status (if available), physical activity (if available), region (if available), and eigenvectors (GWAS data only). Analyses from individual studies were conducted separately and then combined by meta-analysis of 16,097 children and adolescents (15,352 whites, 478 African Americans, and 267 Asians). $I^2$ values are also given. High- and low-intake groups were defined by medians of each dietary intake in each study. Medians of total energy intake ranged from 1,160 to 2,422 kcal/day, medians of protein intake ranged from 12.9\% to 16.8\%, medians of carbohydrate intake ranged from 44.2\% to 59.0\%, and medians of fat intake ranged from 28.0\% to 41.0\% across studies.
region, study design, dietary intake assessment method, and adjustment for physical activity (all \( P \) for heterogeneity > 0.11).

We did not find substantive evidence for interactions between \textit{FTO} variant and total energy intake (\( P \) for interaction = 0.20), carbohydrate intake (\( P \) for interaction = 0.98), or fat intake (\( P \) for interaction = 0.89) on BMI (Table 2 and Supplementary Figs. 6, 7, and 8). The heterogeneity among studies was low (\( I^2 = 0\%, 15\%, \) and 5\%, respectively). In analyses stratified by levels of dietary intake, associations between \textit{FTO} variant and BMI were similar in high- and low-intake groups (Table 2).

In addition, since there was little or no heterogeneity in interactions between \textit{FTO} variant and dietary intake on BMI across studies, the results were similar when we performed meta-analyses using the random-effects method (Supplementary Table 7).

**DISCUSSION**

We confirmed the association between an index SNP in the \textit{FTO} gene, rs9939609 (or its proxy), and BMI in white
children and adolescents and in all participants combined, but did not detect significant association in African American or Asian children and adolescents. This might be due to the relatively small sample size used by studies of African Americans or Asians included in the current analysis and/or to different linkage disequilibrium patterns across FTO intron 1 between different ethnic groups, particularly in populations of African ancestry (4,51). Other index SNPs within FTO locus might be needed in future studies of African American children and adolescents.

Although studies of FTO association with dietary intake in adults have been more numerous and often better powered with larger sample sizes than similar studies conducted in children and adolescents, the reported results have been inconsistent (16–20,25–34). Our and other studies even observed an inverse association between FTO variant and total energy intake in adults, which might be partly due to under-reporting of total energy intake among individuals with a higher BMI (19,20,39). In the current analysis, we demonstrated an association between the BMI-increasing allele of the FTO variant and higher total energy intake. However, we did not observe a significant association between FTO variants and percentages of energy derived from protein, which has been observed in adults (39), or other macronutrients.

An apparently stronger, and more consistently reported, effect of FTO on total energy intake in children and adolescents could have several explanations. The influence of social desirability bias and the under-reporting issues are smaller in children than in adults (52–54). It is possible that the effect of FTO variation on appetite may be stronger in children and adolescents than in adults. Consistent with this hypothesis and with the idea that FTO genetic effects might vary over the life course, previous studies (49,55–60) have reported an increasing effect of FTO variants on BMI from early childhood to adolescence, with a subsequently decreasing effect throughout adulthood. Our result is also consistent with this, as we observed a stronger association between FTO variant and total energy intake in studies of older children than in studies of younger children.

Several lines of evidence from animal and in vitro studies are consistent with the observed association between FTO variant and total energy intake in humans. It has been reported that overexpression of Fto in mice led to increased food intake (5), and Fto expression in hypothalamus was regulated by feeding, fasting, and energy restriction (61–67). Further studies showed that glucose and amino acid deprivation decreases Fto expression, suggesting a role of FTO in cellular nutrient sensing (68,69), possibly acting via hypothalamic mammalian target of rapamycin pathways known to regulate food intake (70). A recent study (71) suggested a link among FTO, ghrelin (a key mediator of ingestive behavior), and impaired brain food-cue responsivity in both animals and humans. Interestingly, a recent study (9) has challenged the established view of FTO as the major gene associated with BMI and risk of obesity, reporting that the region of FTO intron 1 harboring the BMI-associated variants are strongly associated with IRX3 gene (500 kbp downstream of FTO intron 1) expression in cerebellar brain samples. However, it has been pointed out that the cerebellum is not primarily involved in food intake or appetite regulation and FTO expression may function in a site-dependent manner (72). In addition, another study (10) suggested that RPGRIPL, located >100 bp 5’ in the opposite transcriptional orientation of FTO, may be partly or exclusively responsible for the obesity susceptibility signal at the FTO locus.

One novel finding of our study is the interaction between the FTO variant and dietary protein intake on BMI. The effect size of FTO variant on BMI in children with a low–protein intake was much smaller than in children with a high–protein intake, suggesting that low–protein intake may attenuate the influence of FTO variation on BMI. A study of 354 Spanish children and adolescents reported a significant interaction between the FTO-rs9939609 variant and dietary saturated fat intake on BMI (38), and several adult studies also found interactions between the FTO variant and total fat or saturated fat intake on BMI and obesity risk (20,26,34), while no significant interaction between the FTO variant and dietary intake was observed in our meta-analysis of adult data (39). In addition, we previously found that dietary protein intake might modify the effects of FTO variants on changes in body composition, fat distribution, and appetite in a 2-year weight-loss trial (73,74). A recent mouse study (6) showed that loss of Fto gene altered protein utilization and body composition; and consistently, other studies (68,69) also suggest that FTO may influence body composition through cellular sensing of amino acids. Given the increasing evidence supporting the role of FTO in protein metabolism and body composition, future investigations on this topic might help to clarify the mechanisms underlying the observed interaction between the FTO variant and protein intake, and its effect on BMI.

Major strengths of our study include a large sample size of >16,000 children and adolescents from 14 studies, a wide range of studies with data from early childhood to late adolescence, and the standardized analytical plan across studies. There are some limitations in our study. Our analysis was conducted based on cross-sectional data. Measurement errors in dietary assessment are inevitable since self-reported data on dietary intake are all subject to bias. We only included dietary data on total energy and macronutrient intake, but no data on specific foods or more specific types of fatty acids or micronutrients, which may potentially interact with the FTO variant as suggested previously (26,34,38). We were unable to examine other adiposity proxies, but were limited to the consideration of BMI, which cannot distinguish body composition and does not give any indication about body fat distribution. To the best of our knowledge, this is to date the largest analysis of FTO variant and dietary intake in children and adolescents, though more data are needed to further
confirm our results. In particular, most of the children and adolescents included in our analysis are individuals of European ancestry (95% of all samples), and it is unknown whether our results can be generalized to other ethnic groups.

In summary, we demonstrated an association between the BMI-increasing allele of FTO variant and total energy intake based on data from 16,094 children and adolescents. Our data also show that dietary protein intake may modify the influence of FTO variants on BMI, offering new insight into the interrelationships between FTO genetic variants, dietary intake, and obesity.

Acknowledgments and Funding. There was no specific funding for this project. Funding sources for the individual authors and for the studies included in the analysis are listed as follows. The ALSPAC study was supported by Medical Research Council grant MC_UU_12013/1-9. The APEX project was supported by National Institutes of Health (NIH) grant HL64972. The authors thank Haidong Zhu, Bernard Gutin, Inger S. Stallmenn-Jorgensen, and Yanbin Dong (Georgia Prevention Center, Georgia Regents University, Augusta, GA) for their contributions to conducting the study and data collection. The BAMSE study was funded by The Swedish Research Council, The Swedish Heart-Lung Foundation, Stockholm County Council (ALF), and the SFO Epidemiology Program at Karolinska Institutet. The GENDAI study was partially supported by a research grant from Coca-Cola Hellas. The GENR study is being conducted by the Erasmus Medical Center and Erasmus University Rotterdam in close collaboration with the Municipal Health Service Rotterdam area, Rotterdam, and the Stichting Trombosezienst inr Enseringlastrust Rijnmond, Rotterdam. The authors thank the children and their parents, general practitioners, hospitals, midwives, and pharmacies in Rotterdam for their contribution. The generation and management of GWAS genotype data for the Generation R Study were performed at the Genetic Laboratory of the Department of Internal Medicine, Erasmus Medical Center, the Netherlands. The authors thank Karol Estrada, Dr. Tobias A. Knoch, Anis Abousseiris, Luc V. de Zeeuw, and Rob de Graaf for their help in creating GRIMP, BigGRID, MediGRID, and Services@MediGRID@Desk (funded by the German Bundesministerium fuer Forschung und Technology, grants 01 AK 803 A-H, 01 IG 07015 G) for access to their grid computing resources. The authors also thank Mila Jhamal, Manoushka Ganesh, Pascal Arp, Marijn Verkerk, Lizbeth Herrera, and Marjolein Peters for their help in the creation, management, and quality control of the GWAS database. Also, the authors thank Karol Estrada and Carolina Medina-Gomez for their support in the creation and analysis of imputed data. In addition, the authors thank Henriette Moll for her support in calculating the dietary intakes. The Generation R Study receives financial support from the Erasmus University Medical Center, Rotterdam, and The Netherlands Organisation for Health Research and Development (ZonMw). V.W.V.J. received an additional grant from ZonMw (ZonMw VIDI: 016.136.361). Additional support was provided by a grant from the Dutch Kidney Foundation (C08.2251). The GHS study team thanks the following: Helmholtz Zentrum München-German Research Center for Environmental Health, Institute of Epidemiology I, Munich (J. Heinrich, H.E. Wichmann, S. Sausenthaler, C.-M. Chen, E. Thiering, C.M.T. Tiesler, M. Schnappinger, and P. Rehak); Department of Pediatrics, Marien-Hospital, Wesel (D. Berdel, A. von Berg, C. Beckmann, and I. Gross); Department of Pediatrics, Ludwig Maximilians University, Munich (S. Koletzko, D. Reinhardt, and S. Krauss-Etschmann); Department of Pediatrics, Technical University, Munich (C.P. Bauer, I. Brockow, A. Grübl, and U. Hoffmann); IUF-Leibniz Research Institute for Environmental Medicine, Düsseldorf (U. Krämer, E. Link, and C. Cramer); and the Centre of Allergy & Environment, Technical University, Munich (F. Behrendt). The LISA study team wishes to acknowledge the following: Helmholtz Zentrum München-German Research Center for Environmental Health, Institute of Epidemiology I, Neuberger (J. Heinrich, H.E. Wichmann, S. Sausenthaler, C.-M. Chen, and C.M.T. Tiesler); University of Leipzig, Department of Pediatrics (M. Borte); Department of Environmental Medicine and Hygiene (O. Herbarth); Department of Pediatrics, Marien Hospital, Wesel (A. von Berg); Bad Honnef (B. Schaaf); UFZ-Centre for Environmental Research Leipzig-Halle, Department of Environmental Immunology (I. Lehmann); IUF-Leibniz Research Institute for Environmental Medicine, Düsseldorf (U. Krämer); and Department of Pediatrics, Technical University, Munich (C.P. Bauer and U. Hoffmann). This work was supported financially in part by the “Kompetenznetz Adipositas” (“Competence Network Obesity”), which is funded by the German Federal Ministry of Education and Research (FKZ: 01G0826) and by the Munich Center of Health Sciences (MCHEALTH). The LACHY project was supported by NIH grant HL64157. The LEIPz2G study was supported by German Research Council (DFG) CRC 1052 “Obesity Mechanisms” 070, the Integrated Research and Treatment Centre (IFB) Adiposity Diseases, the European Commission Seventh Framework Programme (FP7/2007-2013) project Beta-JUDO under grant agreement no. 279153, and the LIFE-Leipzig Research Center for Civilization Diseases, University Leipzig, subproject B1 LIFE Child, funded by the European Union, by the European Regional Development Fund (EFRE), and by the Free State of Saxony within the framework of the excellence initiative. The PANIC study was financially supported by grants from the Ministry of Social Affairs and Health of Finland, the Ministry of Education and Culture of Finland, the University of Eastern Finland, the Finnish Innovation Fund Sitra, the Social Insurance Institution of Finland, the Finnish Cultural Foundation, the Juho Vainio Foundation, the Foundation for Paediatric Research, the Paavo Nurmi Foundation, the Paulo Foundation, the Diabetes Research Foundation, the City of Kuopio, the Kuopio University Hospital (EVO-funding no. 5031343), and the Research Committee of the Kuopio University Hospital Catchment Area (the State Research Funding). The authors thank Professor Satoshi Sasaki at the University of Tokyo for dietary assessment and Naoko Okayama of Yamaguchi University for genotyping in the SHUNAN study. The SWS study was supported by the Medical Research Council, the British Heart Foundation, the Food Standards Agency, and Arthritis Research UK. The authors thank the members of the Southampton Women’s Survey team, including Cyrus Cooper, Keith Godfrey, and Sian Robinson, and the team of dedicated research nurses and ancillary staff. The authors thank the participants in the Southampton Women’s Survey, who gave us so much of their time. The STRIP study was financially supported by the Academy of Finland (grants 206374 and 251360), the Juho Vainio Foundation, the Finnish Foundation for Cardiovascular Research, the Finnish Cultural Foundation, the Ministry of Education and Culture of Finland, the Sigrid Juselius Foundation, the Yrjö Jahnsson Foundation, the C.G. Sundell Foundation, Special Governmental Grants for Health Sciences Research, Turku University Hospital, the Foundation for Pediatric Research, and the Turku University Foundation. The TEENAGE study has been cofinanced by the European Union (European Social Fund [ESF]) and Greek national funds through the Operational Program “Education and Lifelong Learning” of the National Strategic Reference Framework (NSRF)-Research Funding Program: Heracleitus II. Investing in Knowledge Society Through the European Social Fund. This work was funded by the Wellcome Trust (grant 098051). The authors thank all study participants and their families, as well as all volunteers for their contribution to this study. T.O.K. was supported by grant no. DFF-1333-00124 from the Danish Council for Independent Research. V.B. is supported by the Unity Through Knowledge Fund CONNECTIVITY PROGRAM (“Gaining Experience” grant 2A) and the National Foundation for Science, Higher Education and Technological Development of the Republic of Croatia (BRAIN GAIN-Postdoctoral fellowship).

Duality of Interest. No potential conflicts of interest relevant to this article were reported.

manuscript. O.Q. and L.Q. are the guarantors of this work and, as such, had full access to all the data in the study and take responsibility for the integrity of the data and the accuracy of the data analysis.
