Abstract

Background: Tissue inhibitor of metalloproteinases-1 (TIMP-1) has anti-apoptotic functions, which may protect TIMP-1 positive cancer cells from the effects of chemotherapy such as docetaxel and gemcitabine. The purpose of the present study was to evaluate TIMP-1 immunoreactivity as a prognostic and predictive marker in advanced breast cancer patients receiving docetaxel (D) or gemcitabine plus docetaxel (GD).

Methods: Patients with locally advanced or metastatic breast cancer who were assigned to D or GD by participation in a randomized phase III trial were included in the study. Assessment of TIMP-1 status was performed retrospectively on primary tumor whole-tissue sections by immunohistochemistry and tumor samples were considered positive if epithelial breast cancer cells were stained by the anti-TIMP-1 monoclonal antibody VT7. Time to progression (TTP) was the primary endpoint. Overall survival (OS) and response rate (RR) were secondary endpoints. Associations between TIMP-1 status and outcome after chemotherapy were analyzed by Kaplan-Meier estimates and Cox proportional hazards regression models.

Results: TIMP-1 status was available from 264 of 337 patients and 210 (80%) of the tumors were classified as cancer cell TIMP-1 positive. No significant difference for TTP between TIMP-1 positive versus TIMP-1 negative patients was observed in multivariate analysis, and RR did not differ according to TIMP-1 status. However, patients with TIMP-1 positive tumors had a significant reduction in OS events (hazard ratio = 0.71, 95% confidence interval (CI) = 0.52-0.98, $P = 0.03$). Additionally, a borderline significant interaction for OS was observed between TIMP-1 status and benefit from GD compared to D ($P_{\text{interaction}} = 0.06$) such that median OS increased by nine months for TIMP-1 negative patients receiving GD.

Conclusions: TIMP-1 status was an independent prognostic factor for OS but not TTP in patients with advanced breast cancer receiving either D or GD. There was no statistically significant interaction between TIMP-1 status and treatment, but a trend towards an incremental OS from the addition of gemcitabine to docetaxel in patients with TIMP-1 negative tumors suggests further investigation.

Background

In advanced breast cancer, chemotherapy is used for patients with estrogen receptor (ER) negative, endocrine resistant, or rapidly progressive disease to offer symptom control and improve survival. Whether to use combination chemotherapy or a sequential single agent chemotherapy strategy remains unclear. Combination chemotherapy is associated with higher response rates (RR) and improved time to progression (TTP) but the survival benefit is at its best modest and often linked with increased toxicity [1]. Therefore there is a need for tools that can identify those patients who will benefit the most from combination chemotherapy.

Breast cancer is recognized as a heterogeneous disease and response to treatment seems to depend on molecular characteristics of the tumor, some of which confer resistance to specific drugs while others confer a more multiresistant phenotype covering several different drug classes [2-8]. Predictive markers may serve as tools for tailoring therapy for individual patients, yet the number of clinically useful markers is still limited [9-11].

Tissue inhibitor of metalloproteinases-1 (TIMP-1) is a multifunctional protein, where some of its functions are related to the inhibition of matrix metalloproteinases (MMPs) while other biological functions are MMP-independent, such as inhibition of apoptosis and stimulation of proliferation [12-16]. A prognostic value of TIMP-1 in primary breast cancer has been suggested in several studies, with high plasma or tumor tissue content of TIMP-1 being associated with poor patient outcome [15-19]. Moreover, breast cancer patients with TIMP-1 positive cancer cells [2,8,20,21] seem to benefit less from adjuvant anthracycline-containing chemotherapy. Docetaxel (D), a taxane disrupting the dynamic function of microtubules [22], and gemcitabine (G), a pyrimidine analog arresting DNA replication and synthesis [23-25], are widely used in breast cancer therapy [26,27]. A phase III clinical trial by the Danish Breast Cancer Cooperative Group (DBCG) [28] compared the efficacy of D versus GD in patients with locally advanced or metastatic breast cancer. GD increased TTP by two months compared to D alone, while RR and overall survival (OS) were similar [28]. The purpose of the present study was to assess the potential predictive and prognostic information provided by TIMP-1 in patients participating in this trial. We have previously shown a differential benefit in these patients from the addition of G to D depending on intrinsic molecular subtype [29], and consequently we additionally sought to clarify whether a possible effect of TIMP-1 was independent of intrinsic subtypes.

Methods

Patients

The present study was based upon a DBCG randomized, phase III, multicenter trial previously described in detail

[28]. The trial compared the efficacy of D to the combination of GD in 337 patients with histologically confirmed locally advanced or metastatic breast cancer. Patients were randomly assigned to D (100 mg/m² day 1, every 21 days, or G (1000 mg/m² days 1 and 8 plus D (75 mg/m² day 8, every 21 days. Patients were either previously untreated, had received prior (neo)adjuvant chemotherapy or a single prior chemotherapy regimen, mostly anthracycline-based, for metastatic breast cancer. The majority of patients had *HER2* normal (68.8%) and hormone receptor positive disease (70.9%). More than half of the patients had visceral disease (57.3%). The type and amount of post-study chemotherapy were similar in the two arms. The study was conducted in accordance with the Declaration of Helsinki, and all patients gave their signed informed consent prior to study entry. DBCG prepared the original protocol as well as the biomarker supplement, and the Danish National Committee on Biomedical Research Ethics approved the original protocol and the supplement (KF 02-045-01 and KF 12 315632/H-KF-02-045-01) prior to activation.

TIMP-1 immunohistochemical staining

Expression of TIMP-1 protein was evaluated on formalin-fixed, paraffin-embedded (FFPE) primary tumor tissue whole sections (3 μm). The validated mouse monoclonal antibody (clone VT7) raised against recombinant human TIMP-1 [30,31] was applied for immunohistochemical (IHC) staining as previously described [8]. In brief, sections were deparaffinized in xylene and rehydrated in graded concentrations of ethanol. For antigen retrieval, the sections were microwave treated in citrate buffer pH = 6 and endogen peroxidase activity was blocked by hydrogen peroxide. Sections were incubated with VT7 (0.25 μg/ml) overnight at 4°C, and the antibody was detected with mouse/rabbit Advanced HRP (Code No. 4068, Dako A/S), and the reaction was visualized with DAB + (Code No. K5007, Dako A/S). TIMP-1 was assessed semi quantitatively using the positive (any cytoplasmic staining of tumor cells, > 0%) versus negative (no staining of tumor cells) staining signal as a measure of the TIMP-1 immunoreactivity in the epithelial breast cancer cells [2,8,20]. The whole-tissue sections were scanned and examined by light microscopy and reviewed blinded, without knowledge of patient characteristics and outcome, by three independent investigators (pathologist EB and two trained observers, technician AB and biologist CLT). The independent scores from all three investigators were consolidated into a final score. In case of discrepancies, agreement was reached by the three investigators evaluating the slides together.

Statistics

Associations between TIMP-1 protein status and prognostic and demographic variables of the main study [28]

and PAM50 intrinsic subtype [29] were assessed. Associations between TIMP-1 and categorical variables (treatment regimen, hormone receptor status, human epidermal growth factor receptor 2 (*HER2*) status, type of metastatic site, stage of disease, previous chemo-, hormonal-, and radiation-therapy, and PAM50 intrinsic subtype) were evaluated by Fisher's exact test, while associations between TIMP-1 and ordinal and interval variables (ECOG performance status, age at randomization, number of metastatic sites, and disease-free interval) were evaluated by the Wilcoxon rank sum test.

Time to progression (TTP) was the primary endpoint in the original trial [28] as well as in this biomarker sub-study, and secondary endpoints were overall survival (OS) and response rate (RR). TTP was measured from date of randomization to date of documented progression with censoring at date of last visit or death. OS was calculated from date of randomization to date of death with censoring for surviving patients at last visit date. Time-to-event endpoints (TTP and OS) were estimated by the Kaplan-Meier method, and associations to TIMP-1 status were evaluated by the log-rank test. Analyses of TIMP-1 were done unadjusted as well as adjusted for preselected covariates in multivariate Cox proportional hazards models. The preselected covariates were those found to be significant in the previous analysis of the main study [28] and in a subsequent correlative sub-study including PAM50 intrinsic subtype [29]: treatment regimen, disease type (visceral vs. nonvisceral), stage of disease, performance status, number of metastatic sites, and PAM50 intrinsic subtype. The adjusted model was further stratified for previous chemotherapy [28]. The assumption of proportional hazards was assessed by Schoenfeld residuals. Subgroup analyses were done to assess whether treatment effects on TTP and OS differed according to TIMP-1 status or the levels of preselected variables. In addition, explorative analysis of treatment effect heterogeneity according to the combined TIMP-1 and PAM50 intrinsic subtype status (TIMP-1 positive and non-basal-like vs. TIMP-1 negative and/or basal-like) was evaluated. The multivariate Cox proportional hazards model was extended by one interaction term at a time. The interaction terms were tested using the Wald test and results were given in a Forest plot. RR was evaluated for patients with measurable disease. The overall RR was defined as a complete or partial response according to RECIST criteria, version 1.0. RRs were compared by using Fisher's exact test.

Statistical analyses were conducted using SAS version 9.2 software package (SAS Institute, Cary, NC, USA). All statistical tests were two sided, and $P < 0.05$ considered statistically significant. Reporting Recommendations for Tumor Marker Prognostic Studies (REMARK) were adhered to wherever applicable [32]. The design of the study

was prospective-retrospective as described by Simon et al. [33].

Results

TIMP-1 IHC staining

Archival FFPE primary tumor tissue blocks from patients enrolled in the trial were retrospectively collected between January 2006 and December 2010 from study sites and centrally stored. The original trial recruited 337 participants, and for the present study a total of 273 tumors were available for TIMP-1 analysis (Figure 1). TIMP-1 IHC staining was successful in 264 patients. The 264 TIMP-1 assessable patients differed significantly from the 73 non-assessable patients ($P < 0.05$) with regard to stage of disease, (neo)adjuvant chemotherapy, adjuvant hormonal therapy, and adjuvant radiation therapy (Table 1). Among the assessable 264 patients, 210 (80%) had a TIMP-1-positive tumor. TIMP-1 status was not correlated with any of the baseline characteristics (Table 2).

Prognosis and response rates

In univariate analyses, TIMP-1 status was not associated with TTP or OS, however, there was a non-significant trend that TIMP-1 positive patients had increased OS ($P = 0.06$) (Figure 2) (Table 3).

Treatment effects in the study population were similar to those found in the original study [28] (TTP: adjusted HR = 0.60; 95% CI 0.42-0.84; P = 0.003; OS: adjusted HR = 0.88; 95% CI 0.67-1.15; P = 0.34) (Table 4).

In Cox multivariate analysis adjusted for regimen, PAM50 subtype, presence of visceral disease, stage of disease, number of metastatic sites, and ECOG performance status, TIMP-1 positivity was an independent prognostic factor with regard to OS (adjusted HR = 0.71; 95% CI 0.52-0.98; P = 0.03) but not for TTP (adjusted HR = 0.82; 95% CI 0.55-1.21; P = 0.31) (Table 4).

RR among the 164 patients with measurable disease did not differ significantly according to TIMP-1 status (Table 5).

TIMP-1 subgroup analysis

In unadjusted analysis an estimated gain in median OS of nine months was seen in the doublet arm compared to the monotherapy arm for patients with a TIMP-1 negative tumor (GD, median OS: 19.9 months, 95% CI = 14.5-28.5; D, median OS: 10.6 months, 95% CI = 7.9-16.5, log rank p = 0.053) (Figure 3A). No difference in OS according to regimen was detected in patients with TIMP-1 positive tumors (Figure 3B).

In multivariate Cox regression analyses adjusted for the preselected covariates no interaction was demonstrated between TIMP-1 status and treatment regimens for TTP (Figure 4A). For OS a borderline significant interaction was demonstrated such that GD improved OS compared to D in patients with TIMP-1 negative tumors (Figure 4B P_{interaction} = 0.06).

Explorative analysis of gemcitabine responsive subgroup

In this trial we have previously demonstrated a substantial reduction in mortality by GD compared to D in

patients with basal-like tumors [29]. In the current study PAM50 intrinsic subtype remained an independent factor in the multivariate analysis with TIMP-1. To compare TIMP-1 as a single marker against the combination of TIMP-1 and PAM50 intrinsic subtype status further explorative analyses were conducted. A total of 87 (33%) patients were classified as G responsive (e.g. basal-like subtype and/or lack of TIMP-1 immunoreactivity). In Kaplan-Meier analysis patients classified as G responsive had a significant improvement in both TTP (GD, median TTP: 10.3 months, 95% CI = 7.7-12.6; D, median TTP: 6.2 months, 95% CI = 4.1-9.5) and OS (GD, median OS: 17.4 months, 95% CI = 14.4-20.7; D, median OS: 10.0 months, 95% CI = 7.9-15.5) if treated with GD compared with D. Multivariate analysis adjusted for patient and tumor characteristics confirmed these results for OS (P_{interaction} = 0.02, Figure 4B) but not for TTP (P_{interaction} = 0.09, Figure 4A).

Discussion

In the present study, TIMP-1 cancer cell immunoreactivity was associated with a reduction in mortality but not with a reduction in TTP events (primary endpoint). Furthermore, in patients without TIMP-1 cancer cell immunoreactivity, we identified a 46% relative reduction in mortality from the addition of G to D compared to single agent D, although this difference was not statistically significant (P_{interaction} = 0.06).

The majority of breast cancer studies on TIMP-1 and association with prognosis and response to chemotherapy have focused on patients receiving adjuvant chemotherapy [2,8,18,20,34], whereas only two studies have included patients with advanced breast cancer [35,36]. These two studies both measured TIMP-1 levels in the

primary tumors using an enzyme-linked immunosorbent assay-based approach and included patients receiving cyclophosphamide/methotrexate/5-fluorouracil or anthracycline-based chemotherapy. In the exploratory study by Schrohl et al. [36] results suggested that patients with high levels of TIMP-1 are less responsive to chemotherapy, but the study did not include an analysis of OS. On the other hand, the second study by Klintman et al. [35] which supports the association of TIMP-1 with objective response to chemotherapy, did not find TIMP-1 to be associated with either progression free survival (PFS) or OS. The results presented in this manuscript suggest that TIMP-1 protein expression in cancer cells in the primary tumor evaluated by IHC is associated with improved OS for advanced breast cancer patients receiving D or GD. The use of different methodologies and regimens does compromise the comparability of studies, and thus, the prognostic significance of TIMP-1 in advanced breast cancer remains unclear.

The predictive value of TIMP-1 in relation to chemotherapy has been evaluated in a few studies [2,8,20,21] but to our knowledge the relationship between TIMP-1 and the effect of G has not been addressed previously in a pre-clinical or clinical setting. In the present study we found a borderline statistically significant difference in OS favoring GD over D alone for patients evaluated as TIMP-1 negative. TIMP-1 negative patients receiving GD increased their survival by almost 50% to a median survival of 19.9 months compared to 10.6 months for patients receiving D only. Whether this survival benefit can be attributed to the addition of G specifically or whether our findings suggest a more general effect of chemotherapy doublets/D containing doublets in advanced breast cancer remains speculative and hypothesis generating. We were, however,

able to identify a subgroup of patients that derived clinically meaningful benefit from combination chemotherapy as compared to single agent chemotherapy using TIMP-1 immunoreactivity although the results did not reach statistical significance ($P = 0.06$).

Preclinical data suggest that the anti-apoptotic functions of TIMP-1 are mediated through the phosphatidylinositol 3-kinase (PI3K)/Akt survival pathway [15,37] and TIMP-1 in this manner protects cancer cells from the effects of chemotherapy and hence cancer cells lacking TIMP-1 would remain sensitive to chemotherapy. Interestingly, the PI3K/Akt pathway has previously been suggested to be implicated in gemcitabine resistance [38]. Other pre-clinical findings suggest that TIMP-1 modifies proliferation by direct regulation of the cell cycle by arresting cells in G1 phase [39]. This could possibly alter the response to cell cycle specific drugs such as G, as the cytotoxic effect of G is associated primarily with specific inhibition of cells in the S phase [25,40]. Furthermore, low levels of TIMP-1 have been associated with sensitivity to anthracycline-[2,8,20,21] and irinotecan-containing therapy [41]. Since anthracyclines are topoisomerase-2 inhibitors and irinotecan is a topoisomerase-1 inhibitor, TIMP-1 may particularly interact with topoisomerase inhibitors. G has been shown to poison topoisomerase I [42,43], suggesting that TIMP-1 can influence the effect of G through this enzyme. Taken together, these findings, along with the results obtained in the present study, make a 'broader' predictive role of TIMP-1 in the treatment of breast cancer likely.

Clinical trials in advanced breast cancer and other solid tumors often use TTP and PFS as primary endpoints and surrogate markers for OS [44,45]. However, an increase in TTP or PFS does not always translate into

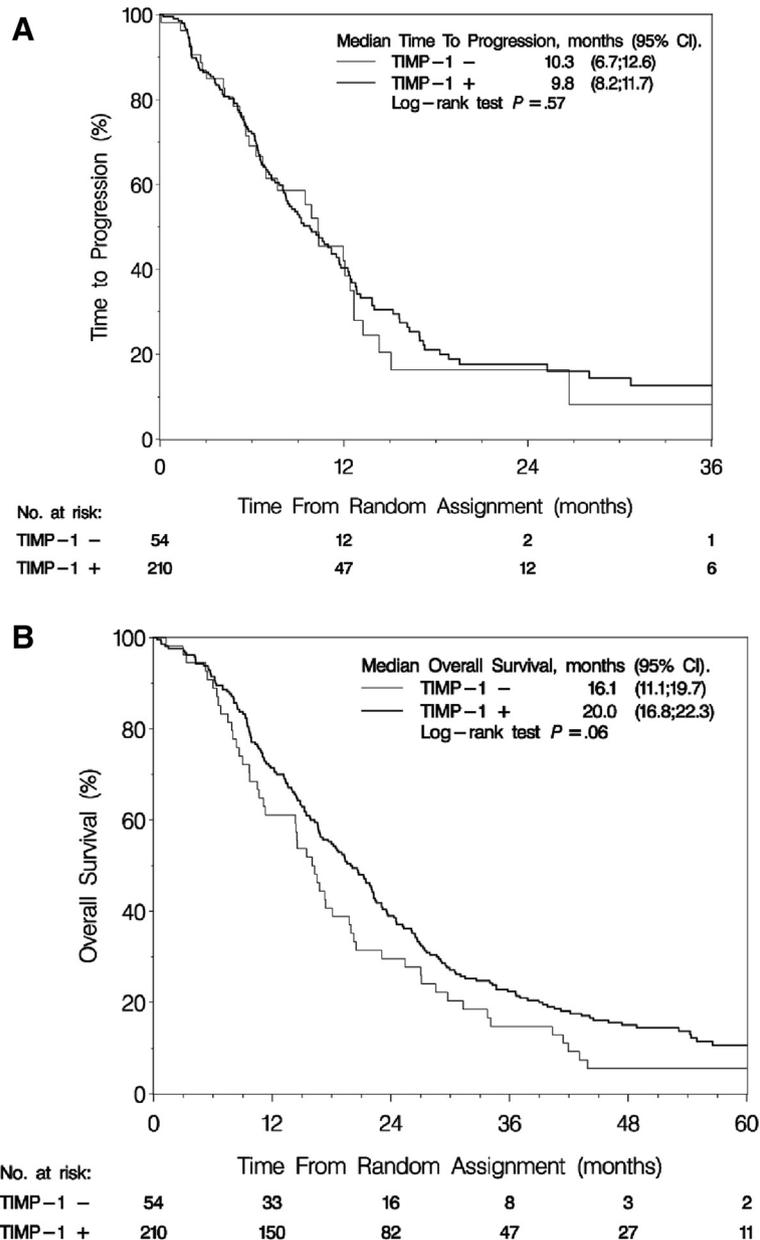

Figure 2 Time to progression and overall survival according to TIMP-1 status. Kaplan-Meier curve for (A) time to progression (165 events) and (B) overall survival (240 events) for all 264 advanced breast cancer patients treated with gemcitabine plus docetaxel or docetaxel alone (study arms combined) according to TIMP-1 immunohistochemical staining status. a survival benefit. On the other hand, the results presented here demonstrate that neither the prognostic impact of TIMP-1 nor the trend of interaction between TIMP-1 status and treatment regarding OS were reflected in the analysis of the primary endpoint TTP. A reason for this discrepancy could be related to the nine-weekly disease-evaluations used in the current trial, which may have generated a systematic bias and less precise evaluation of TTP as compared to the OS endpoint where the date of death is exact [44]. Given that both tumor promoting and inhibitory effects have been described for TIMP-1 [12-16], and that cellular TIMP-1 function depends on the surrounding microenvironment [46,47] the discrepancy between endpoints could also be related to a biological role of TIMP-1 such that the role of TIMP-1 is different in the case of localized cancer

compared to the advanced disease setting, perhaps by preventing further spread of metastasis at this stage.

We have previously shown in this trial a differential benefit from the addition of G to D in patients with a basal-like intrinsic subtype classified by the PAM50 assay [29]. The fact that TIMP-1 status was not associated with PAM50 intrinsic subtype, suggests that TIMP-1 negative status and the basal-like subtype characterize two biologically distinct mechanisms of a possible G responsiveness. For comparison, in an exploratory analysis, we combined TIMP-1 and PAM50 subtype into a panel and classified patients as G responsive if tumors lacked TIMP-1 immunoreactivity and/or were characterized as basal-like, or otherwise as G nonresponsive. Using this panel 33% of the patients could be classified as G responsive compared with 20% and 15% using TIMP-1 status or PAM50 intrinsic subtype classification, respectively. The benefit from GD compared to D was considerably larger in patients with a G responsive profile, and this heterogeneity was confirmed by a statistically significant test of interaction between this panel and treatment for OS. Thus, the PAM50 intrinsic subtype/TIMP-1 protein status panel identifies the patients most likely to benefit from GD compared to D in terms of OS, and additionally, this panel appears to identify and separate two-thirds of the patients unlikely to derive any benefit from this combination therapy.

A strength of this study is that data from 78% of the patients enrolled in a randomized phase III clinical trial with long-term follow-up were available for analysis. In addition, we applied a previously validated assay for TIMP-1 immunoreactivity. On the other hand this study also has some potential limitations. The statistical power was limited due to the small population size, especially

under-powering the results of the subgroup analysis. Another limitation is the fact that we did not include TIMP-1 staining of stromal cells in the analyses. It has been suggested that TIMP-1 may be produced by stromal cells and eventually become absorbed by breast cancer cells [48], and an association between stromal TIMP-1 expression status and progression of cancer has been reported [49,50], although not consistently [51,52].

In the current study TIMP-1 expression was exclusively evaluated in breast cancer cells, and the outcome might have been different if TIMP-1 had been evaluated in stromal cells or in stromal as well as cancer cells. Furthermore, TIMP-1 analysis was performed on primary tumor tissue and not on corresponding metastases. We cannot be sure that the status of TIMP-1 will be the same in the metastases as in the primary tumor since

Figure 4 Subgroup analyses. Forest plots illustrating hazard ratio (HR) estimates of treatment effect with 95% confidence intervals (CI) for (A) time to progression and (B) overall survival comparison between patients with TIMP-1 negative and TIMP-1 positive tumors, basal-like and non-basal-like tumors, TIMP-1 negative and/or basal-like (G responsive) and TIMP-1 positive and non-basal-like tumors (G nonresponsive). Abbreviations: D = docetaxel; G = gemcitabine; TIMP-1 = tissue inhibitor of metalloproteinases-1.

the molecular portrait of the tumor could have changed pronouncedly in the period in between primary diagnosis and recurrence, especially as a majority of the patients received prior treatment. A substantial discordance in ER and *HER2* status between primary and metastatic tumor tissue has been reported [53-55], and a study has demonstrated differences in the immunoreactivity of TIMP-1 in primary breast tumor tissue and the corresponding axillary lymph node metastasis [56]. TIMP-1 expression in primary and metastatic tumor tissue have not been compared, but usage of metastatic tumor tissue could potentially have had an impact on the results.

Conclusions

In summary, this retrospective analysis applied to a prospective clinical trial demonstrated that TIMP-1 status appears to contain an independent prognostic value regarding overall survival in patients with advanced breast cancer receiving chemotherapy. We demonstrated that OS was almost doubled for patients with a TIMP-1 negative status receiving the combination regimen as compared to single agent chemotherapy. However, the test for interaction between TIMP-1 status and treatment did only reach borderline significance. Furthermore, we could not show a similar reduction in TTP events, the pre-specified primary endpoint of this study. The results presented here need further validation in order to obtain convincing evidence that TIMP-1 may be used as a predictive marker to direct the use of G in combination with D for patients with advanced breast cancer.

The authors declare that they have no competing interests.

Authors' contributions

BE, EB, NB, CB and CLTJ made contributions to conception and design of the study. DLN and BE provided access to clinical data on study material, and EB and CLTJ collected the tissue samples. AB performed the immunohistochemical staining. Evaluation of the stainings was performed by EB, AB, and CLTJ. KDB performed the statistical analysis. All authors contributed to analysis and interpretation of data. CLTJ and CB drafted the manuscript, and all authors contributed to the manuscript preparation and in revising the manuscript critically. All authors read and approved the final manuscript, and are accountable for all aspects of the work.

Acknowledgements

This work was performed as part of the Sino-Danish Breast Cancer Research Centre which is funded by the Danish National Research Foundation and the National Science Foundation of China. Support was also obtained from A Race Against Breast Cancer and Danish Center for Translational Breast Cancer Research. CLTJ received financial support from The Research Council of Herlev University Hospital and The Research Fund of Department of Pathology of Herlev University Hospital. The authors wish to thank statistician Maj-Britt Jensen at DBCG for critical review of the manuscript.
