There is significant interest in the synthesis of large molecular aggregates due to their interesting physical properties and beautiful crystal structures.1,2 One of the main goals in the area of molecular magnetism involves the development of new methods for the utilization of magnetically interesting compounds as building-blocks for the construction of large clusters and multidimensional coordination polymers.2,3 Despite the significant efforts to achieve this target, examples of such large clusters based on smaller magnetic clusters are still rather limited.2,4 Amongst the most common building-blocks in manganese coordination chemistry are the homovalent $[\text{Mn}^{III}(\mu_{3}-\text{O})]^{7-}$ and heterovalent $[\text{Mn}_{2}^{III}\text{Mn}^{II}(\mu_{3}-\text{O})]^{6-}$ oxo-centred metal triangles which are often found as the main structural components in large compounds with complex structures.2,5 Efforts aimed at developing high nuclearity clusters based on $[\text{Mn}_{3}^{III} \text{O}]$ sub-units were intensified after the discovery of discrete $[\text{Mn}^{III}(\mu_{3}-O)]^{7-}$ clusters displaying ferromagnetic exchange interactions and single-molecule magnetism (SMM) behaviour,6 the isolation of a family of $[\text{Mn}_{3}^{III}]$ SMMs that includes a member with a record energy barrier to magnetization reversal for transition metal SMMs,7 and several other clusters displaying interesting magnetic properties originating from tightly linked $[\text{Mn}_{3}(\mu_{3}-\text{O})]^{n}$ triangles sharing one or more of their edges.8 More recently there has been significant interest in the construction of oligomeric clusters consisting of covalently linked oxime-based $[\text{Mn}_{3}^{III} \text{O}]^{7+}$ building-blocks. These investigations have afforded some dimeric $[\text{Mn}_{2}]^{2+}$, and tetrameric $[\text{Mn}_{4}]^{4+}$ aggregates displaying tetrahedral or rectangular core topologies.9

We have been interested in the development of new synthetic methods for the construction of high nuclearity Mn clusters. One of these methods, that involves the combination of phenolic oximes with diols, has afforded two structurally impressive complexes that describe a $[\text{Mn}_{12}]$ double-decker wheel,10b and an 1-D coordination polymer containing a $[\text{Mn}_{10}]$ octagonal super-structure.10b We now report the synthesis, structure and magnetic behaviour of the hexameric $[\text{Mn}_{3}^{III}\text{Na}]_{6}$ molecular wheel $[\text{Mn}_{18}^{III}\text{Na}_{6}(\text{sao})_{18}\text{Br}_{12}(\text{H}_{2}\text{O})_{18}(\text{DMF})_{6}]^{2-}$ (1) (sao$^{2-}$ is the dianion of salicylaldoxime) which is the second largest oxime-based Mn cluster known to date, the largest member of the family of molecular oligomers based on $[\text{Mn}_{3}]$ triangles, and the only one with a wheel-like metal topology.

The reaction of $\text{MnBr}_{2} \cdot 4\text{H}_{2}\text{O}$, 2-(hydroxymethyl)phenol (hHpH$_{2}$) and saoH$_{2}$ in the presence of sodium cyanate (NaOCN) in a 1 : 1 : 1 : 1 molar ratio in a 4 : 1 MeCN/DMF solvent mixture leads to the formation of 1 in ~45% yield.§ The molecular structure§ of 1 (Fig. 1 and 2) contains a $[\text{Mn}_{18}^{III}\text{Na}_{6}]$ wheel-like cluster consisting of six crystallographically equivalent oxime-based $[\text{Mn}_{18}^{III} \text{O}]^{7-}$ triangles linked through six Na$^{+}$ ions. The $[\text{Mn}_{18}^{III}\text{Na}_{6}]$ repeat unit of 1 contains one oxo-centred triangular arrangement of three Mn$^{III}$ ions and a Na$^{+}$ ion attached to it via the O-atoms of the soa$^{2-}$ ligands, which occupy the edges of the triangle. The axial coordination sites of the Mn$^{III}$ ions are occupied by one bridging H$_{2}$O molecule, and terminal Br$^{-}$ ions (2), H$_{2}$O (2) and DMF (1) molecules. The Mn$^{III}$ ions are hexa-coordinated with distorted octahedral coordination geometries and all display the expected Jahn–Teller (JT) axial elongation, with the JT axes being perpendicular to the plane of the $[\text{Mn}_{3}]$ triangle. Two $\mu_{3}$-one $\mu_{4}$-sao$^{2-}$, and one bridging H$_{2}$O ligand connect each $[\text{Mn}_{3}^{III}]$ triangle with two neighbouring Na$^{+}$ ions, which in turn are linked to the next

ligands are located outside the [Mn_{18}Na_{6}] wheel, whereas those of the remaining six occupy the central cavity creating a hydrophobic shell (Fig. 2, top). The Mn–O–N–Mn torsion angles are rather small, ranging from 6.4 to 12.9°, in agreement with the values observed for other sao\(_2\)/C0\_based [Mn\(_{18}\)]O triangles.\(^6,7\)

The neighbouring [Mn\(_{18}\)]O sub-units are significantly tilted as revealed from the angle between the planes defined by the Mn\(^{III}\)/O\(_2\) ions of adjacent [Mn\(_{18}\)]O units which is \(\sim 52.2°\) (Fig. 2, bottom). As a result the aggregate of 1 deviates significantly from planarity. The [Mn\(_{18}\)]O triangles are well separated from each other, the shortest inter-triangle Mn···Mn distance being \(\sim 6.23\) Å. Complex 1 is of nano-sized dimensions with an outer diameter of \(\sim 2.8\) nm (Fig. 2, top) and a thickness of \(\sim 0.8\) nm. Clearly, complex 1 is a large cluster and indeed is one of the largest oxime-based Mn complexes known, being smaller only than the [Mn\(_{32}\)] double-decker wheel.\(^10\)

Close examination of the packing of 1 reveals a parallel arrangement of [Mn\(_{18}Na_{6}\)] molecules in the crystal and the formation of columns running along the c-axis of the cell (Fig. S1, ESI†).

The direct current (dc) molar magnetic susceptibility, \(\chi\) (where \(\chi = M/B\); and \(M\) is the magnetization), of polycrystalline 1·3DMF·30H\(_2\)O was measured in an applied magnetic field, \(B\), of 0.1 T, over the 5–300 K temperature range. The data is plotted in Fig. 3 per [Mn\(_{18}\)]O triangle. At room temperature, the \(\chi T\) product of 1 is 7.8 cm\(^3\) mol\(^{-1}\) K. This value is lower than that expected from the spin-only contribution to the magnetism of a Mn\(^{III}\) trinuclear unit (9.0 cm\(^3\) mol\(^{-1}\) K, with \(g_{\text{Mn}} = 2.00\)), assuming that the magnetic properties of 1 arise as the superposition of the magnetic properties of six non-interacting [Mn\(_{18}\)]O units. Upon cooling, the \(\chi T\) product decreases continuously to reach 2.5 cm\(^3\) mol\(^{-1}\) K per [Mn\(_{18}\)]O at \(T = 5\) K. This behaviour is indicative of antiferromagnetic interactions within the [Mn\(_{18}\)]O units. To better define the magnetic properties of 1, variable-temperature-and-variable-field (VTVB) magnetization data were collected in the field range 0.5–7.0 T and in the temperature range 2–7 K. These data are shown as \(M/\mu_B\) versus \(\mu_B B/kT\) in the inset of Fig. 3.

![Fig. 1](image1.png) **Fig. 1** Representation of the molecular structure of 1. Colour code: Mn blue; Na, purple; Br, green; O, red; N, dark blue; C, grey. H atoms are omitted for clarity.

![Fig. 2](image2.png) **Fig. 2** Space-filling representation of the molecular structure of 1, emphasizing its nano-sized dimensions (top). The structural core of 1 highlighting the [Mn\(_3\)] triangles linked through Na\(^+\) ions (bottom). Colour code: Mn, blue; Na, purple; Br, green; O, red; N, dark blue; C, grey. H atoms are omitted for clarity.

![Fig. 3](image3.png) **Fig. 3** \(\chi T\) product of 1 versus \(T\) plotted per [Mn\(_{18}\)]O triangle. Inset: Variable temperature-and-variable-field (VTVB) magnetization data of 1 in the field range 0.5 to 7.0 T and in the temperature range 2 to 7 K. The experimental data are shown as black circles. The calculated curves, obtained from full matrix diagonalization of spin-Hamiltonian (1) for isolated Mn\(_{18}\)O triangles, are shown as solid red lines.
For the interpretation of the magnetic properties of 1, we consider that they arise as a superposition of the magnetic properties of six non-interacting \([\text{Mn}^{III}]\) units. Thus, we used spin-Hamiltonian (1):

\[
\hat{H} = \sum_{i,j \neq i} -2J_{ij} \hat{S}_i \cdot \hat{S}_j + \mu_B \mathbf{B} \cdot \mathbf{S}_i + \sum_i \mathcal{D}_i \left( \hat{S}_i^2 - S(S + 1)/3 \right)
\]

with \(i, j\) running over all \(\text{Mn}^{III}\) centres of a \([\text{Mn}^{III}]\) unit, \(J\) the isotropic magnetic exchange interaction between \(\text{Mn}^{III}\) centres, \(\hat{S}\) a spin-operator, \(\mu_B\) the Bohr magneton, \(B\) the applied magnetic field, \(\mathcal{D}_{\text{MN}} = 2\), the isotropic \(g\)-factor common to all \(\text{Mn}^{III}\) centres, \(D\) the axial magnetic anisotropy of \(\text{Mn}^{III}\), and \(S = 2\). Taking into consideration the crystal structure of 1, we use in our model three distinct exchange interaction parameters \(J_{12}, J_{23}, J_{13}\) reflecting the scalene nature of the triangular \([\text{Mn}^{III}]\) units. The experimental \(\chi T\) product and VTVB magnetization data were numerically fitted to spin-Hamiltonian (1) by use of the simplex algorithm.\(^{11}\) This resulted in the following best-fit parameters:

\[
J_{12} = -6.35 \text{ cm}^{-1}, \quad J_{23} = -2.22 \text{ cm}^{-1}, \quad J_{13} = -0.85 \text{ cm}^{-1} \quad \text{and} \quad D_{\text{MN}} = -2.0 \text{ cm}^{-1}.
\]

The three different best-fit exchange parameter values can be correlated to the three different \(\text{Mn}-\text{N}-\text{O}-\text{Mn}\) torsion angles in the \([\text{Mn}^{III}]\) units, which are smallest between \(\text{Mn}1\) and \(\text{Mn}2\) and largest between \(\text{Mn}1\) and \(\text{Mn}3\). The best-fit curves are shown as solid red lines in Fig. 3. Neglecting the \(\text{Mn}^{III}\) anisotropy, the ground spin-state is an anisotropic, the ground spin-state is an \(S = 1\) state. This is in agreement with previous studies on analogous, isolated \([\text{Mn}_n\text{O}(\text{salen})_3]^{\text{3+}}\) triangles with similar torsion angles.\(^{6,7a,b,12}\) Single crystal hysteresis loop measurements on complex 1 show no sign of SMM behaviour, even at temperatures as low as 30 mK (Fig. S3, ESI!).

Concluding, an aesthetically pleasing nano-sized hexameric wheel-like cluster containing oxime-based \([\text{Mn}_n\text{O}(\text{salen})]^{\text{3+}}\) sub-units is reported. It is the largest member of the recently-developed family of molecular oligomers consisting of \([\text{Mn}^{III}]\) triangles and the only one with a wheel-like metal topology. Complex 1 is also the only oxime-based \([\text{Mn}_n\text{O}]\) \((n > 2)\) molecular oligomer where the sub-units are connected via a diamagnetic metal ion; in all other oligomeric complexes they should provide access to structurally and magnetically novel complexes.

We also thank the University of Cyprus for an internal research grant to AT. EKB thanks the Villum Foundations (Denmark) for a Velux Visiting Professorship.

### Notes and references

§ The diol does not appear in the final product, but its presence in the reaction mixture is essential for the formation of 1. Vacuums-dried solid analysed (C, H, N) as 1-MDMF-3H2O (see also Fig. S2 and the corresponding discussion in ESI!).
